Hierarchical Clustering of Alzheimer's Diagnostic Groups
Unsigned mean Fisher-z connectivity strength (FC)

cells are the MEAN FC of the subjects in each diagnostic group (n = 20/20/20/16/20/20), standardised across the six groups per ROI (ddof = 1)
groups clustered by correlation distance + average linkage over the 246-D profile; ROIs by euclidean distance + average linkage

FC per ROI = unsigned mean Fisher-z strength, mean_{j!=i} |z_ij| (connectivity MAGNITUDE, not signed net connectivity)

clinical progression order: CN -> SMC -> EMCI -> MCI -> LMCI -> AD

bootstrap stability of the branches (1000 resamples of subjects within groups): {CN,MCI} 72%; {SMC,EMCI} 45%; {LMCI,AD} 38%

Descriptive only. Branch heights are distances, not p-values. No ROI x stage test in this project reaches q < 0.05.
