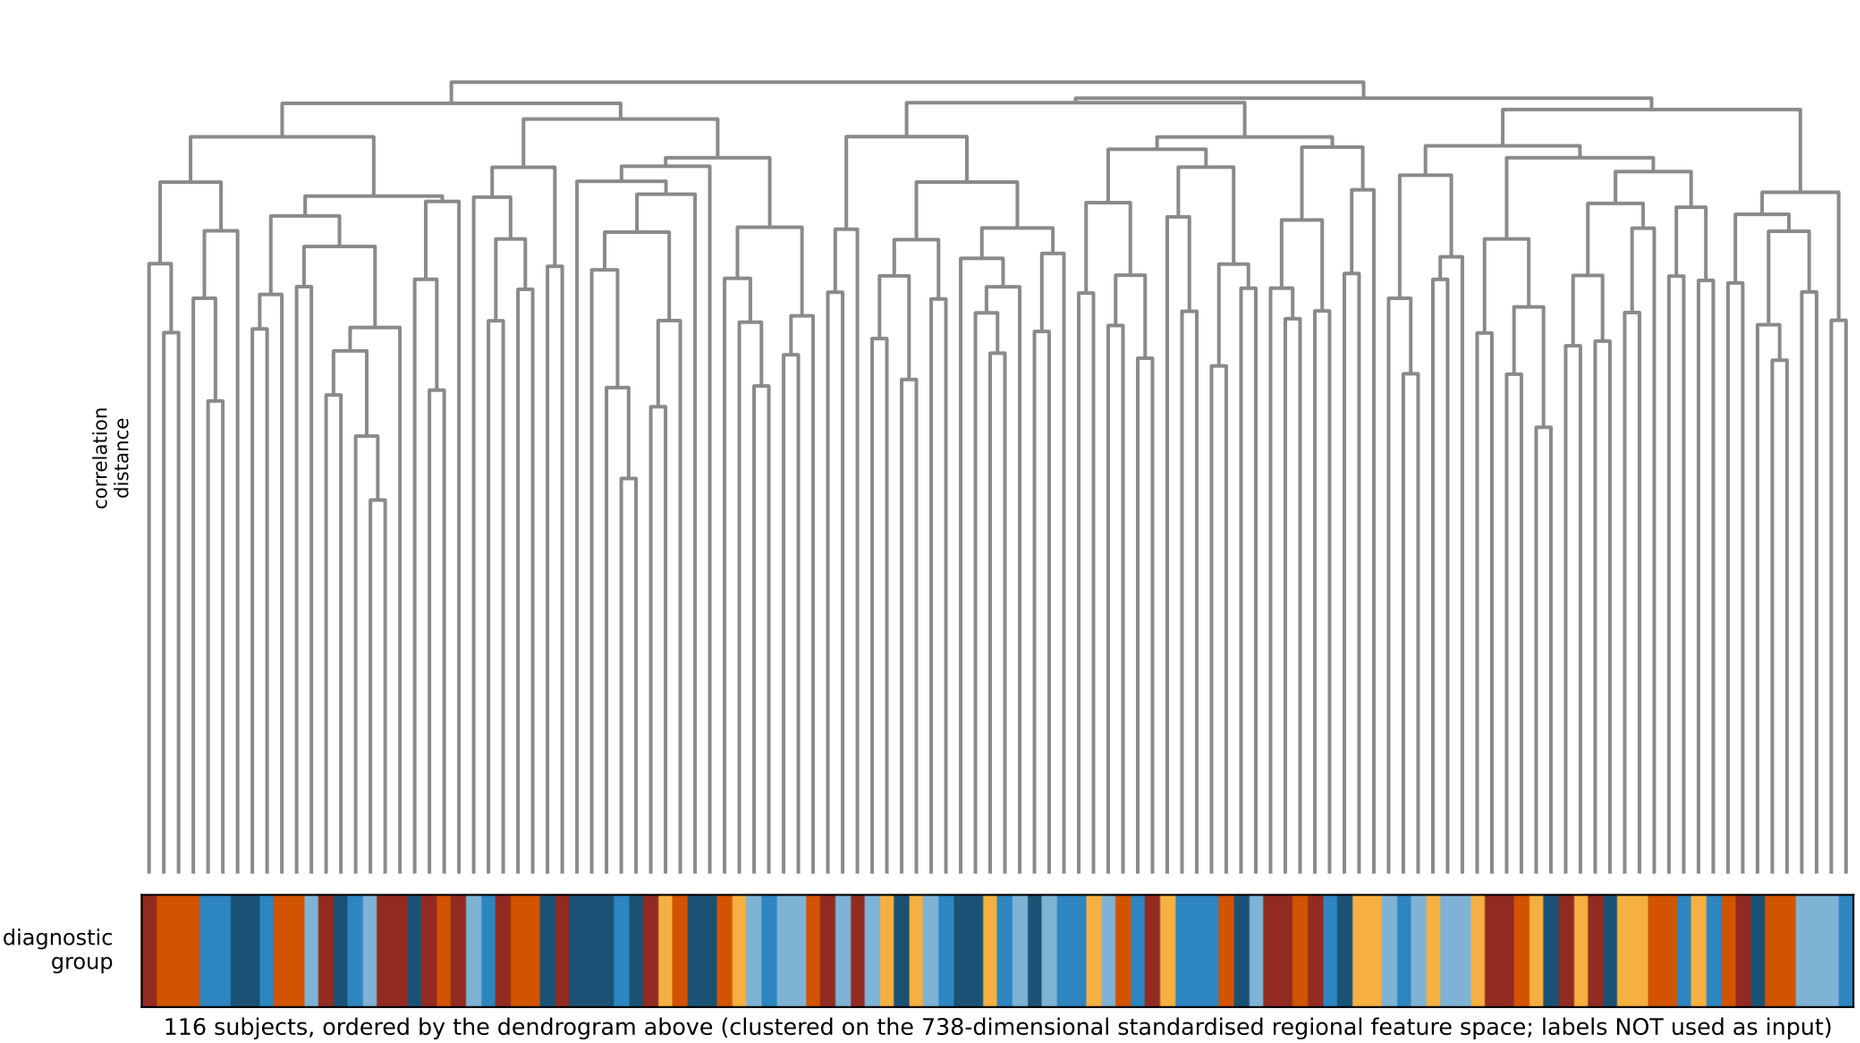
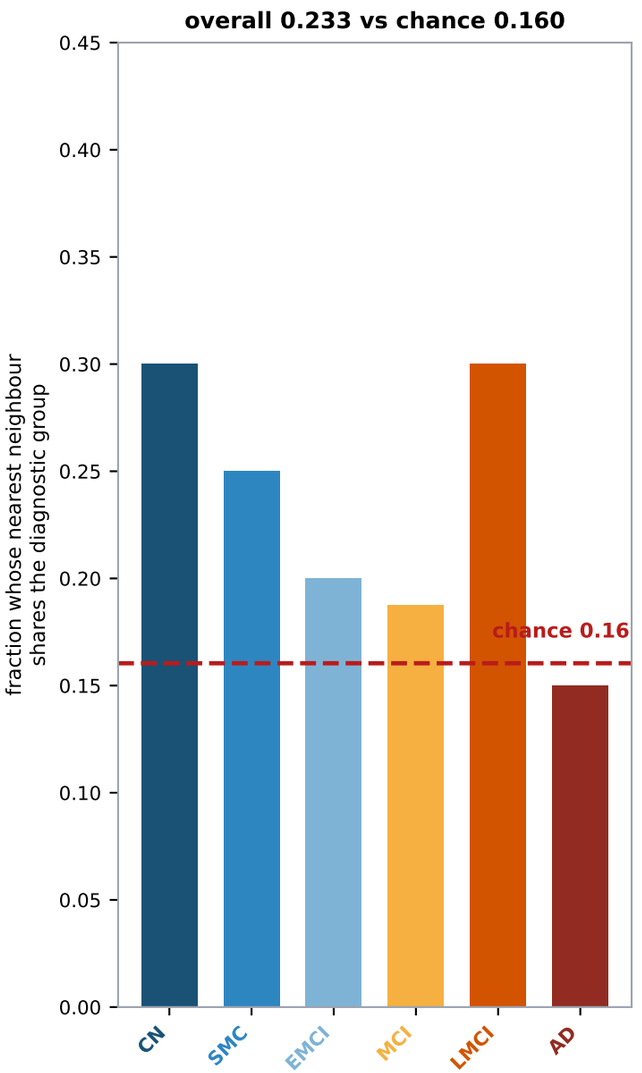
Subject-Level Hierarchical Clustering, Annotated by Diagnostic Group

Subjects are clustered on their own feature profiles; the diagnostic label is shown only as the colour strip and is never an input. Cophenetic r = 0.472.
If subjects of one group clustered together, the strip would show contiguous blocks of one colour.





The nearest-neighbour rate is a descriptive summary, NOT a classification accuracy and NOT evidence of diagnostic discrimination: no model has been trained and no held-out evaluation exists.
