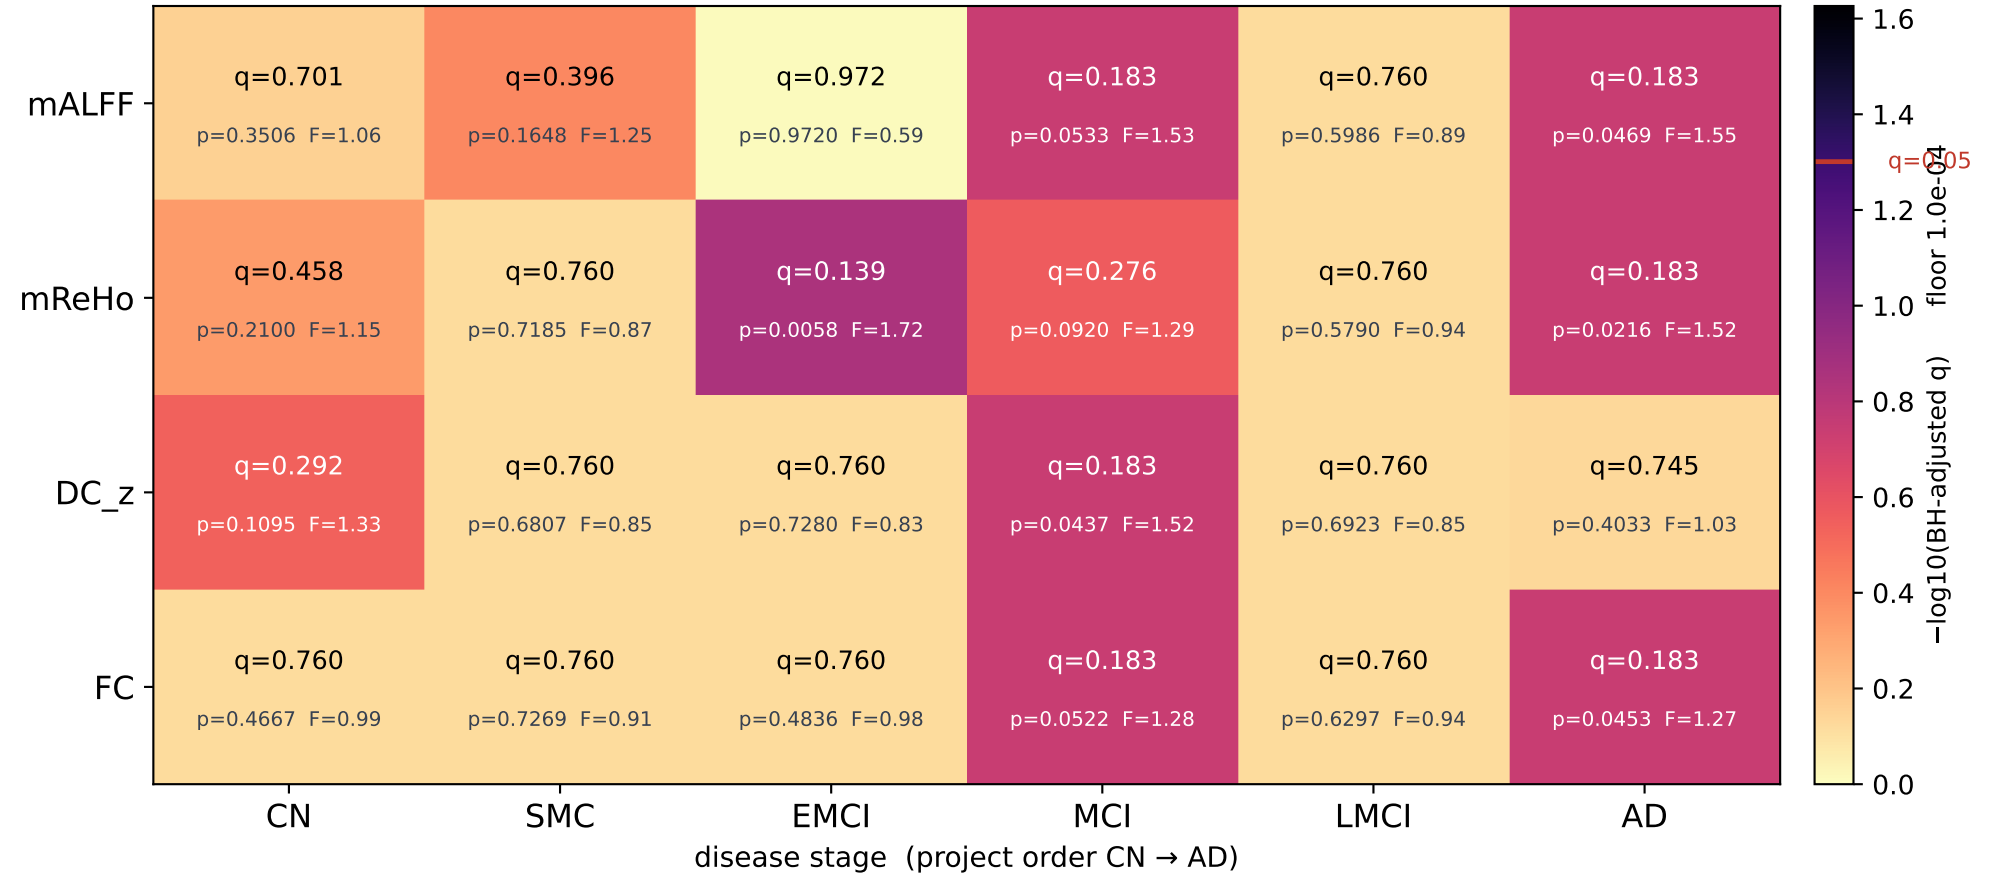
Overall Statistical Significance Across Four Biomarkers and Six Alzheimer's Disease Stages



Each cell is one biomarker-stage one-vs-rest test: that stage's subjects against the other five stages POOLED.
Test: distance-based pseudo-F (two-group PERMANOVA) on z-scored features, 9999 subject-level label permutations, seed 20261013.
FC is represented by its 30135 unique upper-triangle Fisher-z edges (diagonal excluded); regional biomarkers by 246 ROI values.
Benjamini-Hochberg FDR applied across all 24 tests. Colour = −log10(q), floored at 1.0e-04 (the smallest attainable p).
RESULT: NO CELL REACHES q < 0.05. Cohort 6ab68ae6e80f61c2: 116 subjects (CN 20, SMC 20, EMCI 20, MCI 16, LMCI 20, AD 20), one acquisition each.
EXPLORATORY: pooling the other five stages ignores the ordinal structure CN→AD. This is not a test of monotonic progression.
