Alternative View: Hierarchical Clustering of EFFECT SIZE (not significance)

Complement to the P-score figures. Effect size is a measured, signed magnitude that exists whether or not a test is significant, so clustering it groups ROIs by the direction and size of their stage-vs-rest difference. Blue = stage below the pooled rest, red = above. Columns are never clustered.

Effect size is NOT significance: none of these differences survives FDR correction at this sample size. Shown for structure, not for inference.
