P-Score Hierarchical Clustering: ROI-Level Stage-vs-Rest Significance
mALFF

P-score = -log10(q), Benjamini-Hochberg over 246 x 6 = 1476 tests per biomarker; two-sided Mann-Whitney U per ROI per stage
rows clustered by euclidean distance + ward linkage on the 6-D significance profile (cophenetic r = 0.657) -- this groups ROIs by SIMILARITY OF EVIDENCE, not by biology

disease stage, fixed clinical order -- columns are NOT clustered (one-vs-rest: this stage versus the pooled other five)

no ROI passes FDR correction: 0 of 1476 cells reach q < 0.05 (highest P-score 0.652 < 1.301)
