FDR-Adjusted Significance by ROI and Stage
Functional Connectivity

FC is summarised per ROI as the unsigned mean Fisher-z strength FCstr_i = mean_{j!=i} |z_ij|
source is signed and unthresholded; the diagonal is zeroed before summarising; there are no missing edges
the signed row mean was rejected because it equals DC/245 (r = +0.994 with DC_z); the unsigned strength correlates with DC_z at r = -0.090

^ *permutation test on all 246 ROIs jointly -- NOT an ROI-specific p-value; different statistic and different colour scale*

no cell reaches q < 0.05 (0 of 1476 ROI x stage tests)

Two-sided Mann-Whitney U per ROI per stage; effect size Hedges' g (see csv/).
Values plotted are FDR-adjusted q-values. Numerical floor 1e-12 applied before log10.
