Diagnostic-Group Hierarchical Clustering Across All Four Biomarkers — P-Score Profiles

cells are the ROI-level statistical significance of each diagnostic group versus the pooled rest: P-score = -log10(FDR-adjusted q)
groups clustered per panel by correlation distance + average linkage over the 246-D P-SCORE profile; ROI rows are in atlas order and are NOT clustered

columns are ordered by each panel's dendrogram, NOT by disease stage

clinical progression order: CN → SMC → EMCI → MCI → LMCI → AD

No ROI-stage test reaches the significance threshold in any panel: 0 of 5,904 tests at q < 0.05; the largest P-score anywhere is 0.928 < 1.301.

Descriptive only. Branch heights are merge distances, not p-values. The tree reflects similarity of statistical-evidence profiles, not biology or disease progression.
