# ROI-Level Stage-vs-Rest Significance
# mALFF

diagnostic-group clustering by P-SCORE PROFILE  (correlation distance, average linkage, cophenetic r = 0.757)
d = merge DISTANCE (geometric, not a p-value)  q* = permutation q for that contrast, SELECTIVE

columns ordered by the dendrogram above, NOT by disease stage

**clinical progression order:  CN  ->  SMC  ->  EMCI  ->  MCI  ->  LMCI  ->  AD**

**no ROI reaches q < 0.05: 0 of 1476 tests  (highest P-score 0.652 < 1.301)**

Heatmap: two-sided Mann-Whitney U per ROI per stage, Benjamini-Hochberg over 246 x 6 = 1476 tests.
*Branch q: two-group PERMANOVA pseudo-F on subject-level data, 9,999 permutations, BH over the 5 merges. The clusters were DERIVED FROM THE DATA, so this is selective inference -- the q is anti-conservative and descriptive only. No branch is claimed to be significant.
