Hierarchical Clustering of Alzheimer's Diagnostic Groups
Amplitude of low-frequency fluctuation (mALFF) — P-Scores

cells are -log10(FDR-adjusted q) for each ROI and diagnostic group (stage vs pooled rest; BH over 246 x 6 = 1476 tests)
groups clustered by correlation distance + average linkage; ROIs by euclidean distance + average linkage, both on P-SCORE profiles

clinical progression order: CN → SMC → EMCI → MCI → LMCI → AD

COLOUR SHOWS RELATIVE VARIATION WITHIN MALFF ONLY, NOT PROXIMITY TO SIGNIFICANCE.
The darkest cell here is q = 0.223 and the palest is q = 1.000 — the entire colour range sits far above the 0.05 threshold.
Scale tops out at this biomarker's own maximum (0.652); q = 0.05 would require 1.301. Panels are NOT comparable across biomarkers.
No ROI reaches q < 0.05: 0 of 1476 tests. Branch heights are distances, not p-values.
